

Point Calculation Model

$$S_t = \sum_i \sum_j (w_i \times f_{ij}) \times e^{-\lambda_i t_j / 30}$$

t is in units of days.

t_j is days difference from jth day to current day.

j is the day of action taken.

i is type of action.

f stands for total count

i {Action}	w {Weight }	λ (per month)	Reasons
Answering question	0.2	0.1115718	medium significance → baseline
Asking question	0.2	0.1115718	medium: good content but common
Giving an upvote (as actor)	0.2	0.1785148	low-cost action → faster decay
Giving a downvote (as actor)	0.1	0.1785148	low-cost moderation action → faster decay
Attempting an exercise	0.1	0.1785148	low-value, frequent → faster decay
Sharing a note	0.2	0.1115718	medium: content contribution
Creating an exercise	0.5	0.0557859	high-impact → decays slowly (half of baseline)
Gain an Upvote (received)	0.2	0.0892574	slightly more persistent than baseline (0.8×λ ₀)

An Attempt in created exercise (someone attempts your created ex)	0.05	0.2231436	very low per-attempt contribution → fast decay ($2 \times \lambda_0$)
An exercise get approved	0.2	0.0781002	important event → slower decay ($0.7 \times \lambda_0$)
Gain a downvote (received)	-0.2	0.2231436	negative — decays fast so users can recover
Rejection of an exercise	-0.1	0.2231436	negative — fast decay
Banning a content shared by user	$0.2 * N$	0.0200830	rare/related to spam content- very slow decay ($0.18 \times \lambda_0$)

$\Lambda = 0.1115718$ means after one month point decay is 20% from initial points.
